Basic Concepts Columns Beams And

Columns (Image Source Wikipedia) A column can be defined as a vertical structural member designed to transmit a compressive load. A Column transmits the load from ceiling/roof slab and beam, including its own weight to the foundation. Hence it should be realized that the failure of a column results in the collapse of the entire structure.

The design of reinforced concrete columns and beams is very important to provide structural strength to a building and particularly to withstand earthquakes and other natural disasters. Here we look at the design of columns and beams the placement of the concrete and steel and how these give structural strength. We also look at the danger of making columns too small or too thin.

Column:- Column is a compression member usually subjected to combined axial compression and bending 49. 49 3. Beams:- A horizontal bracing member connecting the columns to take care of load and moments 4. Slabs:- RCC slabs are most commonly used in floor and roofs of building. Thickness is small compared will the other dimensions.

Splitting of beam under this situation will be termed as shearing action and force, which will be responsible for shearing of the beam, will be termed as shear force. If we consider one section at the midpoint of beam, we can easily say that shear force will be determined by taking the algebraic sum of all the forces acting either left hand side or right hand side of the section.

The evolution of beam design, in the materials available for use and advancements in the understanding of their behaviour and physical properties, had made it possible to construct the architectural masterpieces of today. To appreciate these achievements the Engineer must have a fundamental understanding behind the choice of material including beam cross section profile and [...]

Load Calculation on Column. What is Beam: The Beam is a horizontal structural member in building construction, which is designed to carry shear force, bending moment, and transfer the load to columns on both ends of it. Beam's bottom portion experiences tension force and upper portion compression force. Therefore, More steel reinforcement is provided at the bottom compared to the top of the beam.

BASIC RULES FOR DESIGN OF BEAMS. While designing R.C.C. beams, following important rules must be kept in mind: Effective Span (Cl. 22.2, IS 456) The effective span of the beams are taken as follows : (a) Simply Supported Beam or Slab. The effective span of a simply supported beam or slab is taken as least of the following:

stirrups are usually one piece of steel that is bent into a rectangular/square/Triangle shape. The stirrup typically wraps around the bottom and top bars of the beams and Columns. A designer should specify the size, spacing and location along the length of the beam or column where the stirrups are required.
